Project Overview: Improve the Scalability & Efficiency of Billing Operations

Goal:

- Help Invitae improve healthcare for billions with genetics
- Provide payment estimations on insurance & patients
- Optimize billing for higher scalability & efficiency

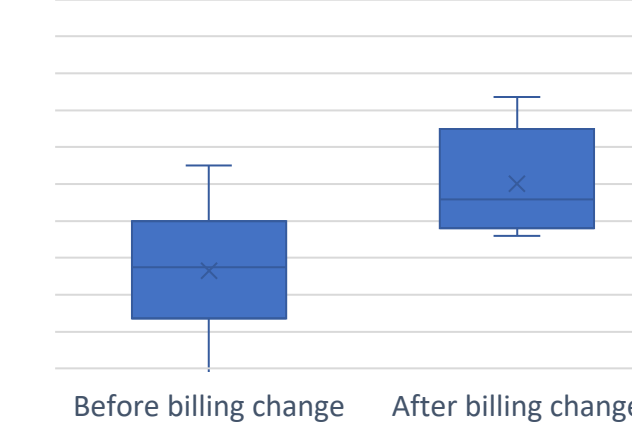

Medical Billing is a complex and uncertain process!

Objective 1: Revenue Analysis with Change in Billing Process

Compare payment amount on all RQs before vs after the change

Investigate metrics change before vs after the change under different groups of RQs

Objective 2: Claim Payout Prediction & Appeals Optimization

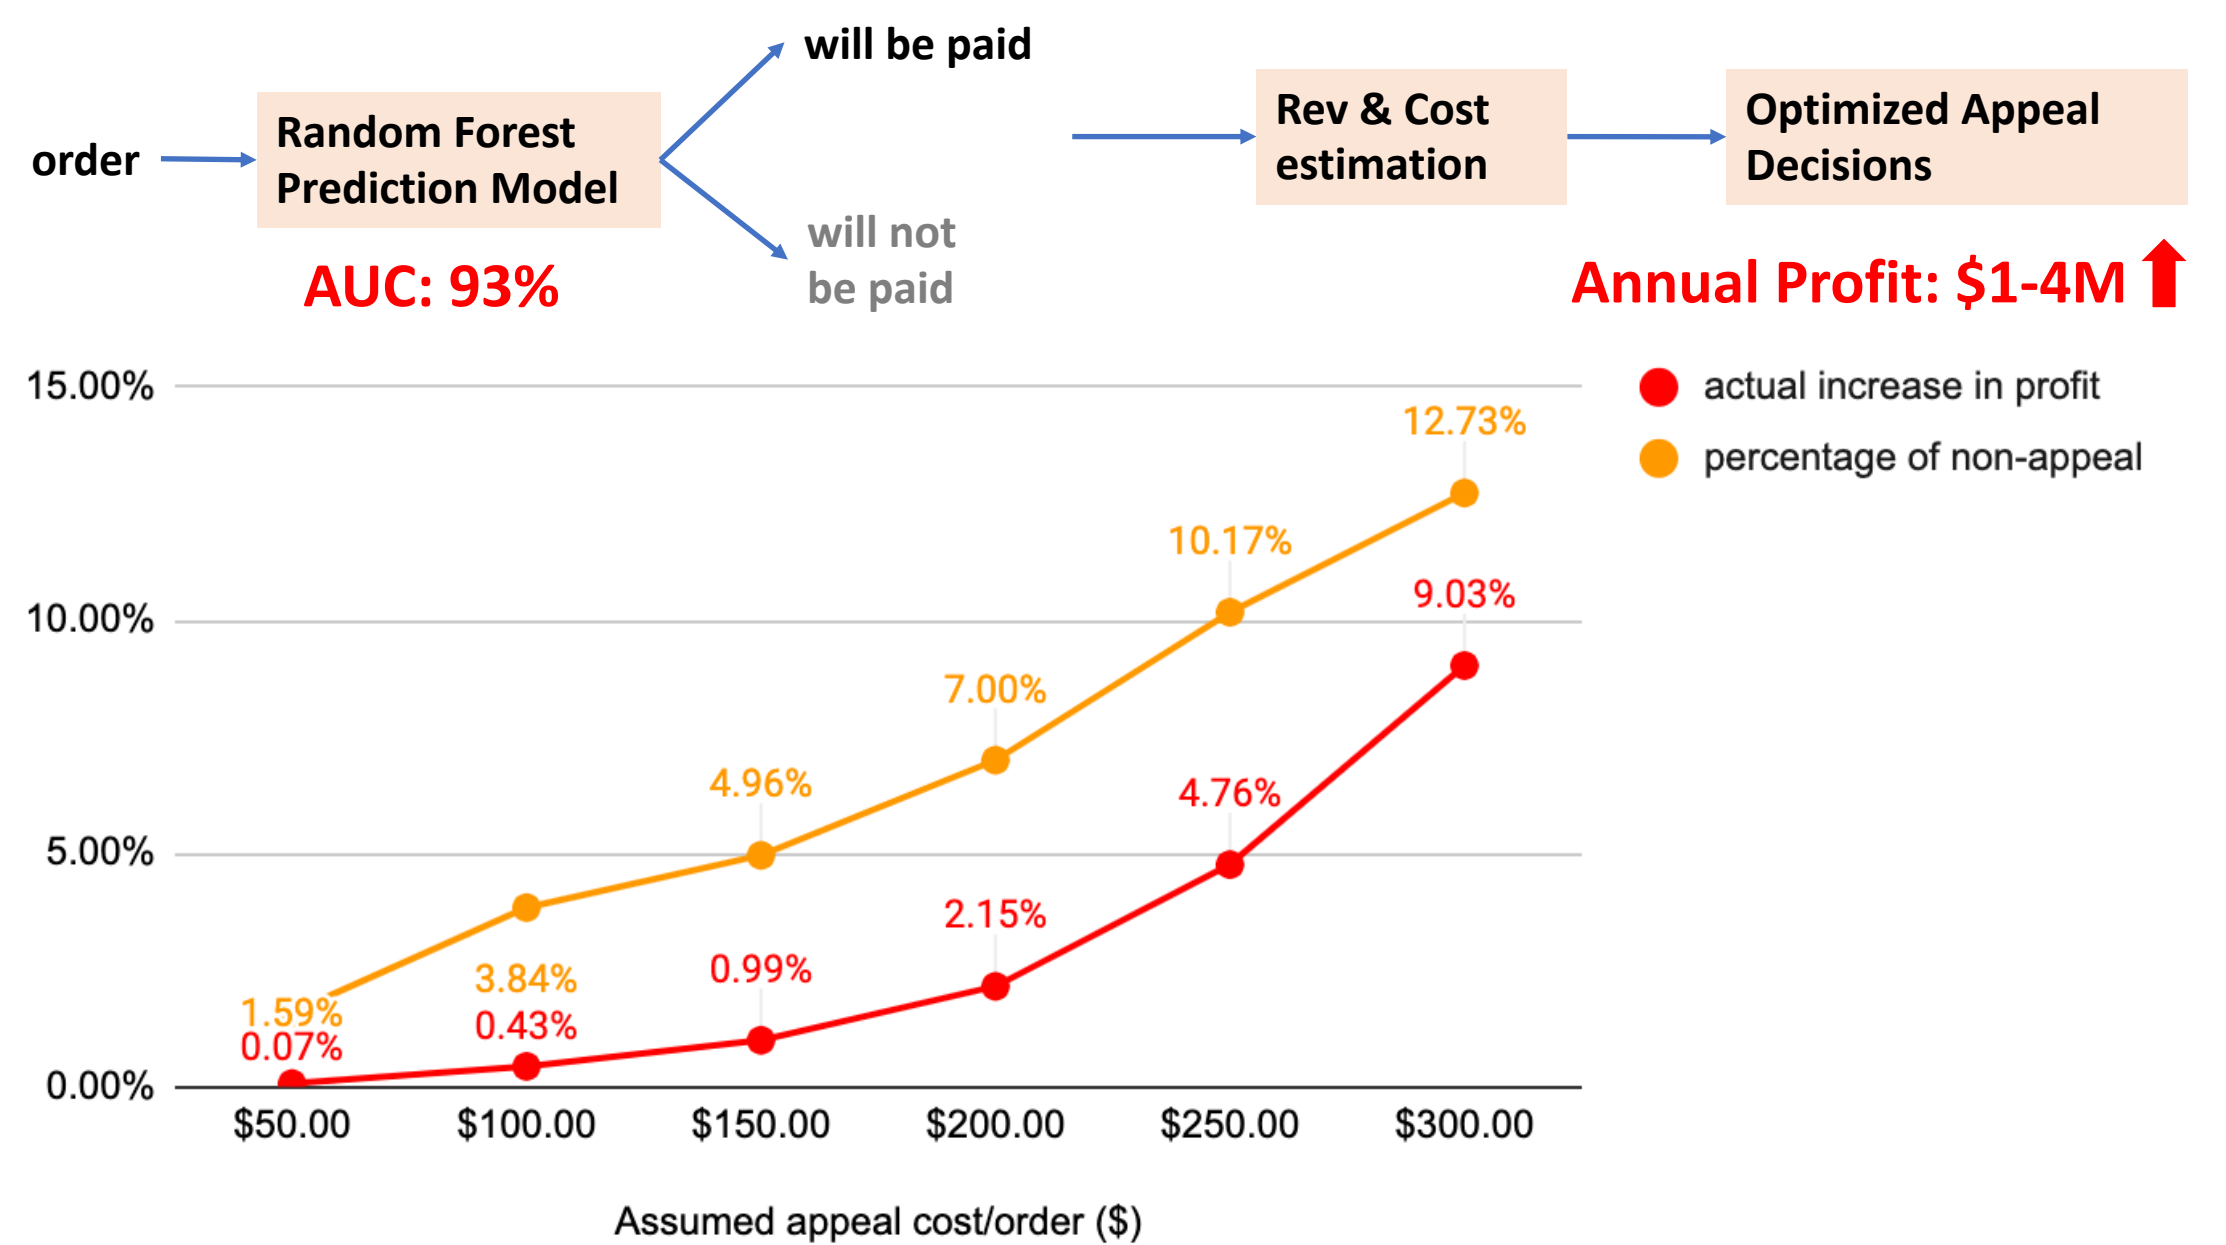

Goals

- Predict order payment results
- Optimize appeals decisions
- Enhance profits & scalability given limited resources

Target Variables	Features	Evaluation metrics
<ul style="list-style-type: none"> • Paid • Paid amount • turnaround time 	<p>Feature set A (upon ordering):</p> <ul style="list-style-type: none"> • Order & Payor info <p>Feature set B (after claims filed):</p> <ul style="list-style-type: none"> • Order, Payor & error info 	<p>Accuracy metrics (prediction):</p> <ul style="list-style-type: none"> • AUC/accuracy/precision/recall <p>Business metrics (optimization):</p> <ul style="list-style-type: none"> • increase in profits

- **Question:** how to reduce unhelpful appeals & save costs?
- **Solution:** Prediction (identification) -> Optimization (prioritization)

- **Baseline (current method):** always appeal
- **Optimized:** only appeal when expected revenues > costs

Objective 3: Patient Out-of-Pocket Estimation

Underestimate Price

Frustration and complaints after the actual price is revealed

Overestimate Price

Patient is uninclined to take the test or switch to competitors

Goal: Provide patients an out-of-pocket estimation that is as close to actual patient responsible payment amount as possible

Data: Primary payor group, primary commercial area, billed price, month of testing, shipping state population ...

Pre-process Data

- One-hot encode categorical variables
- Remove highly correlated variables

Built and fine-tuned models

- Linear regression
- LASSO regression
- Random forest

Adjust model based on previous results

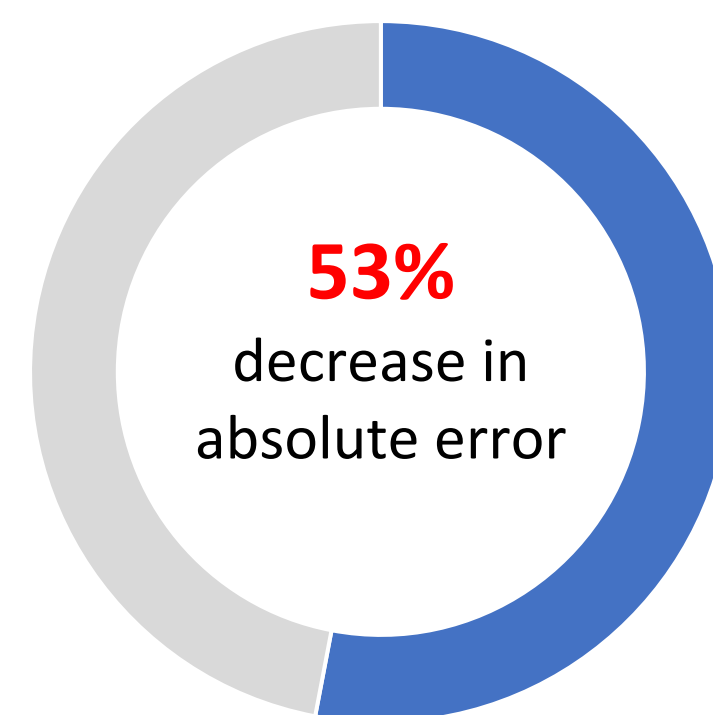

- Stacked model:
 - First classify
 - Then regress

Compare model results

- Compare with:
 - Current estimate
 - Baseline model (predict all to be 0)

More accurate prediction

Stacked Model vs. Current Estimation

Next Steps

Further customer research

Actual price range given to customer

- How wide should the range be?
- Do customers prefer under- or over-estimation?

More customers paying full out-of-pocket amount

Improved efficiency from reduction in manual work

Increased customer satisfaction and retention

Impact

1 Revenue Analysis with Change in Billing Process

Helped the business better define future billing operation policies

2 Claim Payout Prediction & Appeals Optimization

Projected to increase \$1-4M in profits on erroneous orders

3 Patient Out-of-Pocket Estimation

Provided more accurate patient out-of-pocket estimate which would improve customer retention
